Depositional Environments

Besides the Bakken formation being a widespread prolific for when thermally mature, significant producible oil reserves exist within the rock unit itself.

Bakken Formation

Part of the disaster at Lac-Mégantic has been blamed on the fact that much of the highly volatile Bakken oil was mislabeled as lower risk oil and was being shipped in substandard tank cars not designed to contain it. A key feature of MLPs and other neural networks is that they exploit overt and more subtle correlations that exist between the input variables. Reports issued by both the USGS and the state of North Dakota in April 2013 estimated up to 7.

The Bakken Shale indicates a change from highly oxidizing conditions during Three Forks time to highly anoxic conditions in lower Bakken time. The same techniques of horizontal drilling and multi-stage massive hydraulic fracturing are used.

Similarities extend however to the Saskatchewan part of the Williston Basin and the Alberta Bakken. North Dakota, which ranked 38th in per capita GDP in 2001, rose steadily with the Bakken boom, and now has per capita GDP 29% above the national average.

Goldman forecasts well completions will also rise even as the rig count declines, with faster drilling times. Elm Coulee was key to later Bakken development because it combined horizontal wells and hydraulic fracturing, and targeted the dolomitic middle Bakken member rather than the shales of the upper or lower Bakken.

Simultaneously the state of North Dakota released a report with a lower estimate of 2. The Williston Basin extends to southwestern Manitoba, east-central North Dakota, northwestern South Dakota, eastern Montana, and southern Saskatchewan. Although generally similar biomarker signatures indicate an overall genetic affinity and the same source rock for these oils, minor but systematic variations in the biomarker compositions likely reflect regional source organic facies variation or indicate a progressive change in oil maturity.

Importantly, the temperature and how much oil and gas are generated vary as conditions change, and no two source rocks are the same in this regard. In Alberta, the Slave Point Formation, which is stratigraphically equivalent to the Beaverhill Lake tight oil play, has also undergone a limited amount of horizontal drilling and multi-stage hydraulic fracturing in the Otter and Evi Fields, north of the Swan Hills Field. The maximum thickness of Phanerozoic rocks is 16,000 ft.
